

## **Does life exists outside our system?**

If we have 12 planets on our solar system, and one has life. What's the probability that we will find life on other systems? As in vega?

Which systems should we visit first? To know if there is life on other system either we

- choose the closest system

or

- systems with many planets.

Use probabilistic methods (e.g If it has a sun, there's a big probability, to have planets with life)

probabilistics methods

- Planet needs energy

- physics aspects , like gravitic force

- common things with our solar system. Which are? To support life ? unless life is a lot different, doesn't need the things to exist, that we have..like breathing oxygen.

What about search for oxygen related gas? How to bodies get energy? Seems generally assumed, that we need energy one way or the other (oxygen, food, etc)..

Variables on life finding (things that can be used on models, to check if a planet has life).

Minerals (resources ...as in planet resources)

water or substitute for water.

Instead of using models, check the data on computers already present, and search , for it using A.I. Nasa, probably has a lot of data (has like 50 years of data..or more), too technically, or to extense... so use A.I. to query the data..since information is in digital format anyway
