

Riemann hypothesis approach

Problem

Given, the Riemann zeta function, we want to know if all the non trivial zeros, have the real part equal to $\frac{1}{2}$

Abstract

So, we want to prove, that Riemann hypothesis, doesn't hold. Using math function definition (one input, cannot have more than one output)

Proof

Since it's a function, it can't have one input with two objects (definition of function). So, for real part = $\frac{1}{2}$, we can't have two different images. It wouldn't be a function... like different imaginary numbers, on the same real part. You can see this, with the vertical line method. That checks if a function, is a function.

Conclusion

Can't have two zeros, on real part = $\frac{1}{2}$
